```

The effect of changing the length of filter is increase of values, due to the amount of values summed for one average operation. Also, the greater is the filtered length the smaller is the length of the averaged signal.

e) - Function

```
function[smooth signal] = Mateusz Grzybowski function(a,b) % a - this
variable represents any arbitrary signal
                                                             % b - this
variable stands for the filter length
if b <= 1
    disp('The filter length you typed is wrong. Try again.') % This will
inform the user if he entered the filter length properly.
                                                              % Thus, it
solves an error which might occur.
    elseif length(a) <= 1</pre>
        disp('You entered a wrong length of the signal. Please enter some
other length of the signal') % The user is supposed to type in some domain
of the signal, not a single point.
% Hence, it informs user about a problem with his input.
    else
        for c = 1: (length(a) - (b-1)) %This is the for loop which computes
every signal with a chosen filter.
            A = [a(c); a(c+b-1)]; %This is to make the whole function more
clear.
            smooth_signal(c) = mean(A); %this operation evaluates average
for every next b numbers.
                %The output of the function is a vector of values which
                %is actually the a signal filtered with a length b
```

```

```

To sum up, comparing both methods of averaging cycles we are able to conclude some points:

- 1) First method is more accurate, because it sums every possible value to each-other and taking appropriate average of it whilst in the second method some of the points are avoided or calculated twice. This factor might have an impact on the final results of the graph. Fortunately, those differences are not that significant.
- 2) The first method is way faster to write and apply than the second one (in my opinion).
- 3) For ECG50HZ signal, using second method of averaging keeps values more similar to the original curve comparing to the first method. For sure, second method is better here.
- 4) However, for ECG_EMG signal both methods seem to present nearly the same curve which are similar to the original one. Thus, we cannot say whether 1^{st} or 2^{nd} are better here.

Conclusion: 1^{st} method is significantly faster in writing and usage than 2^{nd} method. On the other hand, 2^{nd} method is personally speaking more accurate. If I had to choose which method is better, I think I would choose 2^{nd} one owing to that accuracy is in most cases more important than saving some time on doing something less accurate.
